4.3 Mobility and Air Quality

Indicator 1: Clean Technologies Shared Vehicles

**Rationale:** Conventional fuel burning vehicles release an enormous amount of toxicants to atmosphere, cities must put efforts to introduce a cleaner fuel based shared vehicles.

**Description:** The indicator assesses the percentage of shared vehicles that operate on clean fuels like CNG, LPG, biofuels or are hybrid or electric vehicles.

**Methodology:** The city has to calculate the ratio of annual number of clean technologies shared vehicles to total shared vehicles.

**Formula:**
\[
\text{Percentage of Clean Technologies Shared Vehicles} = \left( \frac{\text{Total number of shared vehicles on clean technologies}}{\text{Total number of shared vehicles in the city}} \right) \times 100
\]

**Note:** "Clean technology shared vehicles consists of vehicles that operate on clean fuels like CNG, LPG, biofuels or are hybrid or electric vehicles"

**Unit:** %

**Performance Evaluation Levels:**

<th>25</th>
<th>50</th>
<th>75</th>
<th>100</th>
</tr>
</thead>
</table>

**Maximum Score:** Total score for the indicator is 100. Cities will be marked in 5 levels with score ranging from 0 to 100.
**Indicator 2: Availability of Public Transport**

**Rationale:** Under Smart City initiatives, most of the cities are planning for organized public transport system. Increase in extent of supply availability of public transport can be a key factor to evaluate the modal shift from private transport to public transport. In turn helps tremendously to reduce emissions by the transport sector.

**Description:** The population growth had put forth a tremendous demand for infrastructure and mismatch between demand and supply of transport infrastructure resulted in delays, fuel loss, air and noise pollution, accidents and loss of productive time and energy. Extent of supply availability of public transport is one of the service level performance benchmarks.

**Methodology:** The city has to calculate the Public Transport Unit (PTU) of total available public transport (which includes fleet size of bus, Metro coach, suburban rail coach and ferries) per 1000 population. Estimated existing population of the city should be considered. Data could either be taken through previous studies, secondary sources or captured through specific primary surveys. Data collected from the primary and secondary sources need to be collated and analyzed.

**Formula:**

\[
\text{Fleet size of PT (bus+metro coach+suburban rail coach+ferries) } \times 1000 \\
\text{Estimated existing population of the city}
\]

Where, 1 metro coach or train coach or ferry = 3 Public Transport Unit (PTU).

Note: Since the capacity of non-bus systems may vary from city to city. Please note the following conversion unit:

- 1 Public Transport Unit (PTU)= 1 standard size bus having capacity 65 passengers
- Midi bus (capacity=45)= 0.7 PTU
- Mini bus (capacity=35)=0.5 PTU

**Unit:** Availability of Public Transport Unit (PTU) per 1000 population

**Maximum Score:** Total score for the indicator is 100. Cities will be marked in 5 levels with score ranging from 0 to 100.

**Performance Evaluation Levels:**

Note: *the decimal figure represents, Public Transport Unit (PTU) per 1000 population
**Indicator 3: Percentage of coverage of Non-Motorized Transport network (pedestrian and bicycle) in the city**

**Rationale:** Developing the Non-Motorized Transport (NMT) network in a city addresses the problems related to the high consumption of non-renewable energies. Thus addressing air pollution and GHG emission production. Furthermore, it promotes aspects like health, user safety, traffic congestion and equal mobility-options for all income brackets.

**Description:** This indicator assesses the network length for dedicated cycle lanes/ tracks and footpath in the city on major road network (all arterial, sub-arterial roads and public transport corridors).

**Methodology:** The city has to calculate the total length of footpath and cycle lanes/tracks. Footpath minimum width and cycle lane/track minimum width should be as per the street design guidelines of MoHUA. In case of narrow roads, width of cycle track and footpath can be combined.

**Formula:**
\[
\text{Percentage of coverage} = \frac{\text{Total length of NMT (footpath + cycle lane/track network)}}{\text{Total road network length}} \times 100
\]

**Unit:** %

**Maximum Score:** Total score for the indicator is 100. Cities will be marked in 5 levels with score ranging from 0 to 100.

Indicator 4: Level of Air Pollution

**Rationale:** Climate and air pollutants including CO2 emissions have a common origin— the current energy model. Both are worsened by the burning of fuel and increase the CO2 emissions. Sound urban planning and clean technologies are now recognised as solutions to air pollution. The smart cities present a unique opportunity to adapt to advanced air-quality-monitoring technologies. Cities are encouraged to adopt affordable technologies by introducing low-cost air-quality sensors and linking the latter to the Integrated Command and Control Centres. This approach can complement the Pollution Control Board’s existing monitoring system to provide further data on localised areas, hot spots and help generate real-time information for cities to take corrective action as well as gauge improvements. Air pollution data will not only help the government in framing policies and measures but allow citizens to make informed decisions that can improve the quality of their lives.

**Description:** A city level air-quality monitoring grid is important to generate holistic data, helps to assess the risks, implements control measures and assesses other climate smart strategies adopted by the city. The city is encouraged to assess to what extent it has achieved National Ambient Air Quality Standards (NAAQS).2009. The National Clean Air Programme sets a target of 20-30 percent reduction of air pollution levels with 2017 as the base year. A city level air-quality monitoring grid is important to generate holistic data, helps to assess the risks, implements control measures and assesses other climate smart strategies adopted by the city.

**Methodology:** The indicator assesses the existing city-level air quality monitoring mechanism, its strengthening requirements and availability of air quality data on public domain. City will be assessed on its additional pollutants monitoring, its reduction strategies, its implementation and compliance to the National Standards.

**Formula:**

Nil

**Unit:** According to National Ambient Air Quality Standard by CPCB

**Maximum Score:** Total score for the indicator is 100. Cities will be marked in 5 levels with score ranging from 0 to 100.

**Indicator 5: Clean Air Action Plan (Planning and Implementation)**

**Rationale:** Unsustainable urban planning, lack of proper waste management, poor technology in industries and increased urban transport have all led to rise in air pollution in cities in India. According to the Health Organisation (WHO), seven million people die prematurely from health risks every year owing to air pollution. The Smart city Mission sets out to bring in its fold the urban policy design of public transit oriented urban mobility, smart parking, intelligent traffic management and integrated multi-modal transport, prioritising non-motorised transport, digitalisation of public services, and waste management e.g. reduction of C&D (construction and demolition) waste, all of which are good practices for better air quality. These are also actions that need to be emulated in the entire city.

**Description:** Cities should take onus for providing healthy air quality to the citizens. Clean Air Action Plans mandated by the National Clean Air Programme (2019) of Government of India integrate the cumulative city level actions for better air quality. For a city to be climate smart it should be able to address the issues of reducing air and climate pollutants since both air and climate pollutants arise from similar sources and addressing one has a direct co benefit to the other. Clean Air is integral for achieving climate smartness by a city.

**Methodology:** Indicator assesses to what extent the city has made efforts to improve the air quality, through clean air action planning and proper air quality management strategy in cities. To generate data and identify sources through scientific methods and subsequently to develop and implement sectoral strategies and projects that are components of the clean air action plan. This has to be done in close co-ordination with the State Level monitoring authorities and other stakeholder departments. The clean air action plan needs to be reviewed and monitored to assess improvements in air quality.

**Formula:**

\[ \frac{\text{Total number of shared vehicles on clean technologies}}{\text{Total number of shared vehicles in the city}} \times 100 \]

**Unit:** %

**Maximum Score:** Total score for the indicator is 100. Cities will be marked in 5 levels with score ranging from 0 to 100.
